STORY 04

Insects

Insects are tiny animals that can be found throughout the world. We can find them in hot and dry deserts, in humid, tropical forests and even in very cold lakes.

Insects do not have a spine. They are protected by a hard shell called an exoskeleton. Because they are so small, they hide in tiny places and they do not require much food to live.

Insects have six legs and many of them have wings and can fly. Flies have only one pair of wings, but many insects have two pairs. The body of insects is divided into three parts: the head, the thorax and the abdomen. Their legs and wings are joined to the thorax and their antennae are connected to the head. There are many kinds of insects. You can find them everywhere.
